

# An Investigation Into the Significant Impacts of Automation in Asset Management

Benjamin L. Britton, David G. Atkinson  
Pearson Business School, London, UK

This paper explores the implications of applying automation, and a technological force in which computer systems can fulfill human tasks, in the asset management industry. The investigation explores a number of significant topics in which managers should begin contemplating, including workforce origination post automation and the primary skills necessary to facilitate augmentation, and how robot advisors could challenge an organisation's value proposition. The investigation was centered on Jupiter Asset Management (JAM) to support their preparations for automation, as well as to provide insight from the "grass roots". Research centered on interviews with experienced individuals within automation and asset management. The first interviewee was Simon Crawford, a Fixed Income, Multi-Asset Performance, and Risk Manager. The second interviewee was Daniel Hulme, CEO of Satalia and Advisor to the UK Home Office. Of crucial importance to the success of this investigation's data analysis before and after the commencement of interviews, was the use of an analytical pattern matching produce, which examined qualitative information. The findings identify that current entry level occupations with systematic and repetitive tasks in a fixed domain, will be automated. Placing a greater demand for analytical abilities in junior recruits as the cognitive understanding of what data represents is a weakness of Artificial Intelligence (AI) thus strengthening augmentation between employees and technology. Automated investment profilers known as robo advisors will challenge the value proposition of organisations, such as JAM, which in time will need to be onboard with the technology to remain competitive within a growing millennial market. The paper concludes that there is an evident need for asset management firms to design training processes that blend enhanced senior level shadowing, with programmes focused on broadening juniors' abilities to interpret and apply AI's generated data through a series of newly identified skills.

*Keywords:* automation, asset management, augmentation, robo advisors, future recruitment, talent development

## Introduction and Research Objectives

The asset management industry presides over the strategic investment of wealth, by attempting to increase deposit values whilst additionally mitigating investment risks through the comprehensive identification of market trends, rigorous analysis of multifaceted data, and logical process of informed decision making. Facilitated through a firm's dedicated "portfolio managers" these services are typically offered to high net-worth individuals or institutions such as pension funds, sovereign wealth funds, or other corporations

(WallStreetOasis.com, 2015). The industry's presence within international financial affairs is exceedingly pronounced, consequently elevating its economic importance. In 2013 the worldwide value of assets under management was estimated at \$87 trillion (approximately one year's global GDP), with PwC forecasting this to escalate to \$100 trillion by 2020 (Bank of England, 2013). As a result of this predicted monetary value growth, it's fiscally important for the intercontinental economy to prevent instability and nurture growth of the industry. It has become ever more apparent in the 21st century that technological innovations will be a pressing managerial issue, contending with this paradigm across many industries. With a critical manifestation and yet challenging innovative technology, what effective managers should take notes of is the notion of automation. Automation is part of a wider Artificial Intelligence (AI) umbrella, which can be defined as "the theory and development of computer systems able to perform tasks that normally require human intelligence" (Patrick, Chollet, & Herzberg, 2016) (p. 2). It takes numerous forms such as Robotic Process Automation (RPA), which formulates reasoning through pattern recognition of large quantities of data. Furthermore there is "autonomics", where systems are able to complete routine tasks by interfacing with existing applications to process transactions and responses faster than a human (Patrick et al., 2016). When discussing the ramifications of automation, it is typical to find individuals focusing on the impact upon manufacturing and other blue collar workflows. However, automative technologies vary and can be implemented into a wide scope of organisational processes. It is thus beginning to transpire that automation can be systematically deployed into professional white collar streams as well. For example, RPA has been brought into service by global wealth advisors, UBS, which is called the SQREEM (Sequential Quantum Reduction and Extraction Model). This delivers customised guidance for their wealthiest clients, by aligning an individual's specific investment preferences to the most suitable financial product, thus substantiating a methodology of how automation could replace some white collar operatives in the bank (Vögeli, 2014).

Although the economic and technological importance of automation has been well documented within blue collar processes, few researches have yet emerged which considers the organisational opportunities, including refined decision making, reduced costs, and improved innovation (Deloitte, 2016); and problems such as employee displacement (Bessen, 2016), which potentially may exist when applying the technology to the white collar sector. As a result, this paper contributes to the literature by investigating automation within the asset management sector, centering on one of the most respectable wealth management firms known as Jupiter Asset Management (JAM). More specifically this paper contributes by serving as a case study that academics and managers alike can reflect upon, in order to prepare themselves for the impacts of automation within the white collar sector.

### **Summary of Literature Themes**

According to Heathfield (2016), an entry level occupation facilitates an individual's ability to penetrate an organisation's workforce with relatively minor experience. White collar organisations, such as JAM, will typically require these persons to have undertaken an undergraduate degree related to their respective industry before employment considerations are made. Entry level tasks are often centered on things which senior figures don't wish or have time to complete. This crucially exposes a new entrant to a wide host of organisational processes, thereby facilitating a broad and multi-disciplined spectrum of talent development that benefits the employee and the host firm.

However, according to Frey and Osborne (2013), a significant number of these entry level positions will

be automated in the coming years. This is further supported by the World Economic Forum (2016), which forecasts a substantial decline in office and administrative job roles by 2020. Consequently, it is plausible to suggest that traditional entry level occupations may be in decline as a result of automation type innovations and technologies. This consequently provokes an emerging managerial issue surrounding the forward looking structure of the firm talent acquisition methods, and the integrity of its talent development process.

In respect of the financial services industry, sizeable occupational growth will dramatically shift towards roles within computing and mathematics (World Economic Forum, 2016). IT roles in general are poised to dominate the top tier of entry level occupations moving forward across multiple industries (Dill, 2015). As a result of these circumstances, the International Data Corporation's prediction that organisational access to data will grow 50-fold over the next decade (Frey, 2014), it's subsequently plausible that data analysis and interpretation roles will become the contemporary foundation of entry level occupation schemes within the wealth management sector, as opposed to data processing. This notion is supported by UKCES (2014) who, in respect of the business and finance profession, states analytical occupations in the future will be of utmost importance.

With regards to the predicted displacement of entry level roles, as a result of automation, the academic literature generally fails to consider what entry level credentials should be regarded as essential in a post automation professional services world. In response to this, this paper proposes the B-PAP model (Britton's Post-Automation Profiler). The B-PAP model helps outline the potential requirements (qualifications, experience, or characteristics) for entry level employees when a high degree of roles, at lower levels in an organisation, are automated. The B-PAP model (Table 1) has been applied to JAM, and the case study sets for this paper, in order to demonstrate its applicability.

Table 1

*B-PAP Model for the Asset Management Industry*

Industry	Key forward looking industry needs for 2020
Asset management	<ul style="list-style-type: none"> <li>Enhanced interpretive capabilities to formulate deep market insights, thus building a superior investment proposition for clients</li> <li>Ability to formulate synergies between large amounts of data acquired by advanced technological processes to find correlations and generate investment opportunities</li> <li>Improved operational efficiency driven by automative processes</li> </ul>
Job level	Typical Occupations of the Level & Industry for 2020
Entry	<ul style="list-style-type: none"> <li>Business &amp; Market Performance Analyst/Junior Data Analyst/Junior Programmer/Database &amp; Networking Junior</li> </ul>
Entry level employees will therefore require	
Qualifications (one option)	<ul style="list-style-type: none"> <li>BA in Finance &amp; investment, as provided by Coventry University (2016)</li> <li>BSc in Data Science, as provided by The University of Warwick (2016)</li> <li>BSc in Software Engineering, as provided by De Montfort University Leicester (2016)</li> </ul>
Experience (multiple options)	<ul style="list-style-type: none"> <li>Demonstrated financial prowess, by potentially making small investments in publicly traded companies</li> <li>Data analysis and arranging information into insightful arrays, by potentially using data visualisation software</li> <li>Programming, by potentially developing their own smartphone apps</li> <li>System and process development, by potentially collaborating in the building and or maintenance of servers</li> </ul>
Characteristics (all)	<ul style="list-style-type: none"> <li>Inquisitive/diligent/analytical/logical/agile/technologically astute</li> </ul>

For managers it is evident that convergence between their human employees and modern automated

counterparts will be essential in creating synchronous and valuable workflows. To facilitate this contemporary method of operation, it is arguable that augmentation is the primary optimisation route as supported by Davenport (2015). Broadly speaking, augmentation encourages a collaboration between humans and machines to complement each other's strengths, whilst to compensate for each other's weaknesses (Davenport & Kirby, 2015). The MIT Economist, Autor (2014), denounces commentators who repeatedly overemphasize the use of automation as a mechanism for success, stating the challenge of instituting a machine that possesses flexibility, judgement, and common sense similar to a human is "immense".

It's apparent that machines do have some comparative disadvantages to humans, and it is plausible that asset management organisations, like JAM, will need to re-configure its employees' current key skills to remedy overarching computer weaknesses, thus designing a modern workforce that can facilitate vigorous augmentation. According to Gray (2016), the top skills needed by employees by 2020, in an era known as the AI driven the Fourth Industrial Revolution, will largely focus on "creativity" while "quality control" could be potentially removed. Therefore, it is evident that to establish affluent automation, management will need to prioritise the enhancement of humanistic soft skills and social abilities in its employees, across a wide range of industries, rather than just hard technical skills such as programming. This notion is supported by the work of Davies, Fidler, and Gorbis (2011), who also placed a significant emphasis on human interactive skills in their top 10 future abilities needed for employees' talents by 2020.

Gray's (2016) prediction on the top skills required of employee by 2020 is a good start yet and it is non-industry specific. As a result, this paper is built on the work of Gray (2016) by considering the skills and abilities required of employees, for the asset management industry, within the AI driven by the Fourth Industrial Revolution. The 10-ES Model (Table 2) is a conceptual application of the top skills thought to be required, in the emerging Fourth Industrial Revolution, for the asset management industry. The framework conceptually prioritizes the skills that may need to be obtained to allow organisations to fully capitalise on the introduction of automated entry level roles. In this paper's theoretical prediction, the more humanistic soft skills have been placed within the higher rankings to compensate for AI's lack of emotive understanding.

Whilst automative technologies emerge as an electrifying opportunity for managers to empower the value proposition of their firms, so does it arise as a challenging force. In respect of the asset management industry, this is evident in the fruition of "robo advisors" (RAs). As a defining trend of 2014 onwards, RAs allow firms that use complex algorithms to leverage a client's information and then formulate tailored investment recommendations by executing highly diversified, automative investment portfolios at lower costs when compared to traditional asset management firms (Hougan, 2015). RAs have shown unprecedented growth, with the leading eleven wealth management organisations increasing the total assets under management by RAs to 65%—this was equivalent to an time with high value of \$19 billion by the end of 2014 (Miller, 2014). Whilst this monetary valuation is notable, and it is also negligible against the total assets under management of Vanguard—one of the world's largest investment firms, who controlled \$3 trillion at the end of 2015 alone (The Vanguard Group, 2016).

Nevertheless, according to Vincent, Laknidhi, Klien, and Gera (2015), RAs will cause significant disruption in the wealth management industry for a variety of reasons. Firstly their substantially lower fees will open the market to mass consumers (with assets under \$200k), who seek affordable financial assistance with a healthy return. Secondly, RAs will cater towards the digital preferences of millenials (individuals born post

1980), who seek greater control of their funds at anytime, anywhere. Finally, the technology will also reduce barriers to entry, as “Robo SMEs” will surface more often to challenge established organisations with incumbent value propositions.

Table 2

*10-ES Model for the Asset Management Industry*

Industry: Asset management		
Target year: 2020		
Rank of importance	Skill	Justification
1 (Most important)	Emotional intelligence	• Ability to understand the emotive needs of clients will be a key differentiator to empower sales, and AI’s most prominent weakness
2	Negotiation	• Important to enable portfolio managers to broker mutually favourable terms for the firm and its client in an AI competitive market
3	Co-ordinating with others	• Important to ensure each operation within the firm plays its part in delivering the promised results
4	Creativity	• Empower humans to develop contemporary offerings and innovative uses of AI as a competitive force
5	People management	• Important to nurture augmentation between humans and machines
6	Service orientation	• Important to find correlations in research data, which could lead to profitable investments and value proposition growth
7	Complex problem solving	• Necessary to accomplish challenging objectives. AI will assist staff in forming best practice solutions
8	Cognitive flexibility	• Create adaptability in planning and thinking, when AI’s identifying in more efficient ways of operating
9	Programming	• Important to build and maintain modern AI, however machine learning will become ever more able to improve itself
10 (Important)	Logical reasoning	• Important to understand the consequences of AI’s proposed actions

Whilst UK high street banks, such as Lloyds, Santander, and Barclays, are planning to launch RAs into the mass market (Dunkley & Arnold, 2016), Allianz (2015) indicates that specialised asset management firms will in the short term choose to ignore this phenomenon. This is because the majority of Baby Boomers (individuals born between 1946 and 1964) and GenXers (individuals born between 1965 and 1980) will still desire a humanistic relationship within their financial affairs. These two generational groups are important as they contain the largest proportion of high net-worth individual investors, at present. However, in the medium term future millennials will start emerging as a larger clientele segment, who will be more likely to be accustomed to the efficient cost and anytime nature of RAs. Consequently, in order to evolve a relevant value proposition whilst maintaining its premium service advantage (i.e. personalised human relationships), it is plausible that JAM, and other asset management organisations, will need to establish a hybrid digital platform (part human, part automation) that aligns with the expectations of millennials (Greenhalgh, 2016).

Whilst the literature concludes that firms such as JAM will need to establish a hybrid digital platform, what is lacking at present is how managers will practically achieve this version of part human, part automation working facilities. In order to assist in this issue, this paper attempts to bridge the gap by applying the Johnson, Whittington, Scholes, Angwin, and Regnér’s (2013) “Buy, Ally, or DIY” matrix (see application below in Table 3). The general principle proposed by Johnson et al. (2013) entails how to achieve a new capability through acquisition, alliances, and organic development. By applying the knowledge derived from previously synthesized literature to the overarching guidance of Johnson et al.’s (2013) model, the research is able to

formulate a premise as to which strategy is most suitable for JAM.

Table 3

*Adapted “Buy, Ally, and DIY Matrix” for JAM and Other Asset Management Firms*

	Buy (acquisition)	Ally (alliance or partnership)	DIY (organic development)	Advised strategy	Justification
High urgency	Fast	Fast	Slow	DIY	Medium term scope of interest would enable JAM to take more time to build a RA platform
High uncertainty	Failures potentially salable	Share losses and retain buy options	Failures likely unsalable	Ally	Unfamiliar territory to JAM Alliance with an experienced specialist will cut risks and bolster knowledge Option to acquire could also be potentially brokered
Soft important capabilities	Culture and valuation problems	Culture and control problems	Cultural consistency	DIY	Enables JAM to build a RA fully around its own mantras, culture, and client expectations
High modular capabilities	Avoid buying whole company	Ally just with relevant partner unit	Develop in new venture unit	Ally	Highly targeted alliances will ensure the use of solely RA technologies with no other commitments

(1) Advised strategies: Buy 0/Ally 2/DIY 2; (2) Ally has more “green advocations” (Johnson et al., 2013); (3) final recommended strategy: Ally.

## Research Methods

As a result of the literature review, three conceptual frameworks were devised along with a host of associated premises, which required expansive research and ultimately ratification. The first was the B-PAP model (Table 1), which aimed to determine plausible traits of entry level employees at lower levels of an organisation, in an era when automaton, within the white collar sector, will be prevalent. The second was the 10-ES model (Table 2), which details a feasible list of prioritised skills needed by entry level employees to allow organisations, within the asset management industry, to fully capitalise on automation in the lower levels of an organisation. In general, the 10-ES model largely promoted the precedence to humanistic soft skills, and thereby synthesising the work of Gray (2016) and Davies et al. (2011). The last premise provided by the literature review considers how managers will establish the automated, predicted capability. Here an application of the Johnson et al.’s (2013) “Buy, Ally, or DIY” matrix was considered. In order to investigate these assertions the study interviewed richly experienced and knowledgeable individuals within the fields of automation and asset management, as a method to clarify and investigate the three conceptual frameworks with empirical evidence.

The first interviewee was Simon Crawford, a fixed income, multi-asset performance & risk manager. Crawford has worked at JAM for 15 years, amassing a deep working knowledge of JAM’s financial products. Crawford also has a profound awareness of macro industry trends that could affect the asset management industry and was therefore an ideal candidate for commenting on the asset management industry’s perception of automation particularly in JAM.

The second interviewee was Daniel Hulme, CEO of Satalia and Advisor to the UK Home Office. Hulme holds an Engineering Doctorate in computational complexity and thus has evidenced academic superiority in this field, presenting an experienced candidate who rendered profound insights on the forward looking ramifications of automation in the asset management industry. Both were interviewed using structured interviews, in order to streamline the discussions into key areas of interest based around the three conceptual

frameworks devised through the literature review. The duplicate use of predetermined questions for each interviewee prevented wastage of resources as well as facilitated truthful comparability between interviewee's responses, as guided by Saunders, Lewis, and Thornhill (2012). To accommodate the investigatory process and establish an academic reference, both interviews have been recorded, transcribed, and stored electronically.

Of crucial importance to the success of this investigation's data analysis before and after the commencement of interviews, was the use of an analytical pattern matching produce, which examined qualitative information. In accordance with this methodology (i) existing or personally developed models (B-BAP, 10-ES as per the literature discussion) were utilised based upon the available literature, (ii) interviews were conducted which examined these assertions within the models devised, (iii) and finally both interview transcripts were interpreted in order to devise conclusions in comparison to the original conceptual models/frameworks. Where interconnected evidence existed between Hulme and Crawford, a valid explanation to support the findings had been identified. Where an unforeseen variable challenged the established thought of the investigations considered in the three conceptual frameworks, further inquiry was initiated so as to establish the reasoning behind its origin and thus developed a deeper level of contributory knowledge (Yin, 2009). The application of matching pattern has proven to be a useful methodology in this investigation. It allowed the evolution of a robust set of research themes and frameworks through a clear framework of academic investigation, which supported the identification of appropriate interviewees (Miles & Huberman, 1994).

## **Results, Discussions, and Conclusions**

### **The Reorganisation of JAM's Talent Development Programmes**

This investigation has found confirmation for the works of Frey and Osborne (2013) in which indeed many typical entry level occupations will be automated, by way of Hulme and Crawford both concurring with this widely accepted notion. Hulme stated that roles which require "systematic, repetitive work in a fixed domain" will be primary operational targets for automation. However, this means how this will impact management and their forward looking talent development protocols is nuanced and highly intriguing.

According to Crawford, if entry level roles are automated, then new recruits will begin a "step up" within the organisation therein altering the firm's structure of career progression and operational formation. With the absence of menial tasks to educate new recruits, Crawford believed entrants would be placed into more extensive in-house training programmes, coupled with a greater degree of senior shadowing thus enabling for a more pragmatic application of education. Some of the contemporaneous academic elements of these training programmes have already been identified. For example, Crawford cites a significant issue with AI that can create a lack of understanding (e.g., operatives are presented with a number but have no comprehension of how it was derived). As a means to answer this challenge, Hulme advocated that all personnel across from entry level to more senior operatives should have a working comprehension of machine learning and AI, therein strengthening an awareness of data analysis processes in which they can further interpret from a humanistic perspective.

In relation to the devised B-PAP model, the evidence largely supports and expands this investigation's theoretical 2020 asset management industry notions. For example, in terms of qualifications, Hulme cites psychological degrees as a credible option, given that management will need to comprehend the human decision making process to design services that resonate with the target audience, and ultimately design a compelling motivation to purchase. Crawford amazingly states that despite asset management firms being white

collar, experience may not be required if a candidate is entering via a programme similar to the current industry wide 2020 scheme, which absorbs gap year and A-level students into the workforce. However, he did additionally cite the importance of maturity and intelligence as characteristics, particularly for some younger 2020 programme recruits.

In conclusion it is recommended that JAM, and other asset management organisations, should recognise and prepare for the loss of current entry level positions, by designing new training protocols that blend extensive in-house training programmes, with a greater degree of senior shadowing thus supporting juniors' abilities to interpret AI's generated data. Prospective applicants to the firm should be considered against the ratified, forward looking B-PAP model.

### **The Definitive Top Skills Needed in Asset Management Industry in the Era of Automation**

In relation to the works of Gray (2016) and the World Economic Forum (2016), a thought provoking contradistinction was identified between the responses of Hulme and Crawford. Hulme advocates the theory of a soft skill prioritisation approach in the design of a proactive, augmented workforce, stating that empathy is a crucial skill that computers lack—a notion that is echoed by World Economic Forum (2016) and Davies et al. (2011). On the other hand, Crawford reverses this perspective, believing computers are only as competent as their programmers and thus the harder technical skills such as coding should be prioritised. The literature of Gray (2016), the World Economic Forum (2016), and Davies et al. (2011) conflict with Crawford's opinion, and thus it should be respectably considered as perhaps an inconsistent or outlying notion. Each perspective during the research process was reflected in the respective 10-ES model answers. Thus confirming the posed assertions.

In conclusion, from the perspectives of Hulme and Crawford with those considered in the literature, there are a number of direct matches and near matches (to/within two allocations of each other) for the 10-ES model conceptualized as part of the literature review (see Table 4 below). As a result, the model is empirically informed and thus should be systematically incorporated into the evolution of JAM's future talent development programmes. Broadly speaking, the softer skills are categorised higher in the rank order of importance, with those becoming narrower, harder, and lower (see Table 4 below).

Table 4

#### *Empirically Derived: Top Skills Needed in the Asset Management Industry for the Era of Automation*

Rank order	Skills of importance	Rank order	Skills of importance
1 (most important)	Emotional intelligence	6	Judgement and decision making
2	Creativity	7	Complex problem solving
3	Negotiation	8	Service orientation
4	People management	9	Cognitive flexibility
5	Coordinating with others	10 (important)	Logical reasoning

### **The Current Existence of Augmentation and How to Enhance It**

Presenting itself as a fascinating acknowledgement, Hulme declared that society is already augmented, exemplifying that individuals cannot immediately access all of human knowledge without a machine (computer and the internet). Consequently this raises a compelling notion that civilisation should not perceive augmentation as a forward looking technology to prepare for but rather businesses already engaged within the methodology. Thus to optimise its advantageous properties, management must evolve augmentation as opposed

to create it, by way of creating faster and more natural ways to engage with the digital world thus propagating better decision making with agility. Hulme declared there are indeed tasks that computers cannot effectively perform such as interpreting the results of analytical processes from empathy based perspectives. For example, Hulme cited that some individuals will not approve of using RAs as their decisions which may be perceived to be unfair or unsympathetic, which as a result will likely always stimulate a demand for human ratification. Within this conjecture. Hulme believes there is a compelling augmentation opportunity to ensure a seamless transition process from machine to a human, thus quelling the individual's concerns and maintaining customer satisfaction. As a result, there is firm evidence for the notion of augmentation as a primary optimisation route as argued by Davenport (2015), and an overemphasis of automative technologies is counterproductive given their empathic weakness as argued by Autor (2014). One meaningful concern that was not previously identified, during the investigation, was the issue of responsibility. Hulme indicated that if a machine was to independently make an inadequate decision, then the implementing firm would be liable for its error. However, by augmenting a human employee with the machine who ratifies all proposed automative decisions, the liability rests with that employee alone. Consequently, this presents an ethically challenging but credible strategy for firms, particularly those that are small and not cash-rich, to reduce their overarching automative liability and exposure to monetary damages.

In conclusion, this project can surmise that augmentation is already largely present in the daily activities of our personal and professional lives. Management should recognise that organisations must now invoke a process of evolving this synergy, rather than supposedly creating one, to orchestrate an ever more seamless customer experience and increase operational efficiencies. The use of humans as mitigating individuals of automative liability is an ethical question that management should consider, against the cultural values of their organisation, their potentially legal responsibilities imposed by law.

#### **Alliance With the Option to Acquire as the Most Effective Strategy to Onboard RA's**

The research conducted here affirms the notion that an alliance is the most appropriate choice to facilitate an RA centric hybrid digital platform. According to both Hulme and Crawford, a strategic alliance or partnership would be the most favourable approach, with Crawford going further to state that the second most appropriate option would be an acquisition and the third would be a DIY option. Crawford believes that if a firm has developed in their maturity and proved the value of their services, alliances are effective in preventing wasting monetary and other resources in discovering whether a technology will be of organisational use. Hulme supported this notion but also urged caution as a strategic alliance or partnership, which could mean numerous firms could end up using the same partner, resulting in a lack of competitive advantage overall residing at any firm. Consequently, this adds favour to the notion of an alliance with the option to acquire later, which both Hulme and Crawford enthusiastically supported.

In conclusion, to acquire an RA capability, it is recommended that JAM, and other asset management organisations, should strategically align or partner with a specialist firm in this field. Furthermore, the partner should demonstrate operational proficiency ideally and an option to acquire the partnering RA organization to develop a competitive advantage. Furthermore, organisations like JAM should implement a seamless transition process for customers who choose to abandon RAs in favour of an empathic human manager.

#### **Future Research**

The potential to extend the results of this investigation through further research is pronounced in two key areas. The first is a providential opportunity to explore how precise augmentation, between RAs and employees, can be nurtured to create faster and more natural expressions of engagement between employees, facilitating enhanced decision making. For example, analysis could be conducted into the properties of incorporating augmented reality technologies within an organisation's working environment, both in terms of facilitating a progressive method of completing occupational tasks and improving a firm's value proposition. The second area presented for future research is an investigation into prospective strategic alliances with the option to acquire, between a large asset management firm, such as JAM, and a flourishing RA organisation in the approach to 2020. This builds upon the papers recommendations, and would compile an additional layer of academic knowledge that firms could utilise in their technological diversification.
